BRANCH OFFICES / PRODUCTION PLANTS

TT PLAST S.A COMPANY IS A POLISH MANUFACTURER OF PLASTIC PIPES AND ACCESSORIES AS WELL AS PVC GRANULATES, WITH OVER 20 YEARS OF EXPERIENCE. OUR PRODUCTS ARE USED IN THE FOLLOWING SECTORS:

ELECTRICAL INSTALLATION

WATER AND SEWAGE SYSTEM

ENERGETICS

GAS

TELECOMMUNICATIONS

VENTILATION AND RECUPERATION

AGRICULTURE

RENEWABLE ENERGY SOURCES

INDUSTRIAL

OUR HISTORY

Start-up. Production of electrical installation pipes and accessories.

Launch of the production of pipes for the energy sector.

Launch of the production of pipes for the water and sewerage sector.

Launch of the production of pipes for the gas sector.

2002

2009

2010

2013

2016

2020

2021

Purchase of the PVC granules production plant in Bieruń.

Purchase of the production plant in Bochnia.

Purchase of the plastic processing plant in Kłaj.

Expansion of the production plant and office building in Targowisko.

Technical information: HDPE chemical resistance

Chemical substances		Level of resistance
Water		+
Acids	Weak	+
	Strong	+
	Hydrofluoric	+
Alkalis	Weak	+
	Strong	+
Inorganic salts		+
Halogens		-
Oxidizers		-
Solvents	Paraffinic hydrocarbons	-
	Halogenated alkanes	⊗

- Non-resistant

PROPERTIES

Technical information	Pe 80	Pe 100	Pe 100-rc
Density	≈940 kg/m ³	950 kg/m ³	950 kg/m ³
Elastic modulus (short-term value)	≥700 MPa	1100 MPa	1100 MPa
Tensile strength at yield	19-23 MPa	25 Mpa	25 Mpa
Elongation at break	≥600%	≥600%	≥600%
Oxidation induction time OIT (200°C)	≥20 min	≥20 min	≥20 min
Resistance to slow crack growth (9,2 bar; 80°C)	≥165 h	1000 h	8760 h
Recommended installation	with sand bedding	with sand bedding	without sand bedding

POLYETHYLENE PIPES - TECHNICAL SPECIFICATIONS

1. PIPES INTENDED FOR THE CONSTRUCTION OF WATER SUPPLY SYSTEMS:

The pipes are made of high-density polyethylene (HDPE).

There are various types of pipes:

- a. single-layer (from materials: PE80, PE100, PE100-RC)
- b. double-layer (from materials: PE100 ; PE100-RC ; PE100/PE100-RC)
- c. three-layer (from materials: PE100 ; PE100-RC ; PE100-RC/PE100/PE100-RC)

The pipes are intended for:

- supply of pressurised water
- supply of drinking water
- supply of pre-treatment water
- supply of water for other purposes
- hydro-transport
- other purposes

2. PIPES INTENDED FOR THE CONSTRUCTION OF SEWERAGE SYSTEMS:

The pipes are made of high-density polyethylene (HDPE).

There are various types of pipes:

- a. single-layer (from materials: PE100, PE100-RC)
- b. double-layer (from materials: PE100 ; PE100-RC ; PE100/PE100-RC)
- c. three-layer (from materials: PE100 ; PE100-RC ; PE100-RC/PE100/PE100-RC)

The pipes are intended for:

- construction of the sewerage system for consumption and utility purposes
- construction of the storm water system
- construction of the vacuum sewer system
- construction of the sanitary sewerage system
- construction of the combined sewer system
- drainage of bridges and overpasses
- hydro-transport
- gravity sewer transfer
- pressure and vacuum drainage and sewerage in the ground
- other purposes

3. PIPES INTENDED FOR THE CONSTRUCTION OF GAS SUPPLY SYSTEMS:

The pipes are made of high-density polyethylene (HDPE).

There are various types of pipes:

- a. single-layer (from materials: PE100)
- b. double-layer (from materials: PE100-RC)

The pipes are intended for:

- construction of the gas supply systems
- supply of gaseous fuels
- other purposes

4. PIPES INTENDED FOR THE CONSTRUCTION OF IRRIGATION SYSTEMS:

The pipes are made of high-density polyethylene (HDPE).

There are various types of pipes: single layer (HDPE).

The pipes are intended for:

- irrigation of croplands
- irrigation of garden squares
- irrigation of orchards
- irrigation of gardens
- irrigation of greenhouses

5. PIPES INTENDED FOR THE CONSTRUCTION OF DRAINAGE SYSTEMS:

The pipes are made of high-density polyethylene (HDPE).

These are double-layer pipes with a corrugated external wall and a smooth internal wall.

There are half- and fully-perforated pipes:

- TP (Totally Perforated) = full drainage pipe (perforation throughout its 360° circumference)
- LP (Locally Perforated) = half drainage pipe (perforation in the upper part of the pipe at 240°)
- MP (Multi-Purpose Pipe) = multi-functional drainage pipe (perforation in the upper part of the pipe at 120°)
- UP - (Unperforated Pipe)

The pipes are intended for drainage of the following spaces and areas:

- public roads, motorways and other
- tracks
- airports
- car parks, manoeuvring areas
- industrial sites, storage yards
- landfill sites
- arable lands and other

6. PIPES INTENDED FOR THE CONSTRUCTION OF THE GROUND-COUPLED HEAT EXCHANGER SYSTEMS:

The pipes are made of high-density polyethylene (HDPE).

There are various types of pipes:

A: Smooth pipes

- double-layer (HDPE on the external wall, HDPE with antibacterial properties on the internal layer)
- at the customer's request, pipes are available in other options (single-, double- or three-layer)

B: Corrugated pipes

- double-layer (HDPE on the external wall, HDPE with antibacterial properties on the internal layer)

The pipes are intended for:

- construction of ground-coupled heat exchangers: Tube, gravel and air heat exchangers

7. PIPES INTENDED FOR THE CONSTRUCTION OF THE HEAT PUMP SYSTEMS:

The pipes are made of high-density polyethylene (HDPE).

There are various types of pipes:

a. single-layer (from materials:) PE100, PE100-RC

Application:

- for the transport of glycol
- for the construction of ground collectors for underground heat pump systems
- for other purposes

ADVANTAGES OF USING POLYETHYLENE PIPES:

- Highly durable and leak-proof joints
- High chemical resistance to most chemical substances
- Constant capacity
- High flexibility allowing for the change of the direction of the pipes
- Low density (compared to steel, cast iron)
- Corrosion resistance
- Reduction of joints due to length of sections (from 12 to 200 metres)
- Temperature resistance
- Fault-free pipelines
- Pipes may be joined using butt fusion and electrofusion welding or mechanical fittings (depending on the pipe diameter)
- PE pipes may be joined with pipelines made of other materials by using flange fittings, PE/steel transition fittings or other suitable mechanical fasteners.

Pipes for water supply and sewerage systems

Made of raw material(s) PE 80

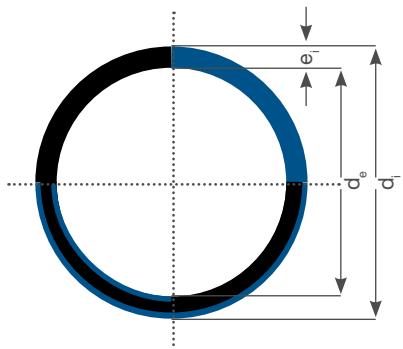

- a. single-layer pipes: blue, black or black with colour stripe

Made of raw material(s) PE 100

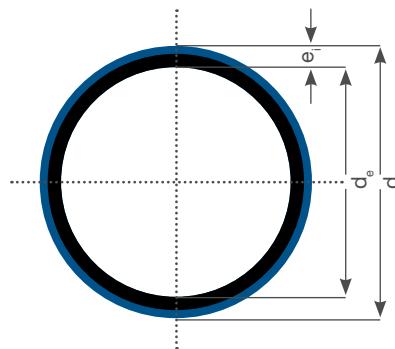

- a. single-layer pipes: blue, black or black with colour stripe
- b. double-layer pipes: blue external layer, black internal layer
- c. three-layer pipes: both blue external layers, black internal layer

Made of raw material(s) 100-RC

- a. single-layer pipes: blue, black or black with colour stripe
- b. double-layer pipes: blue external layer, black internal layer
- c. three-layer pipes: both blue external layers, black internal layer

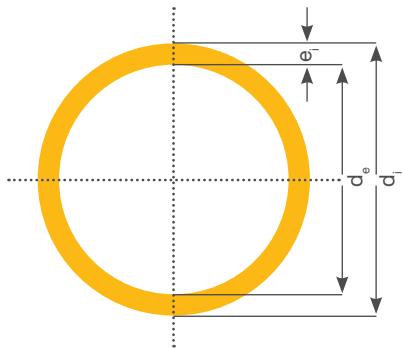

Made of raw material(s) PE 100-RC / PE 100

- a. double-layer pipes: blue external layer (approx. 10%) made of PE 100-RC raw material, black internal layer (approx. 90%) made of PE 100 raw material
- b. three-layer pipes: both blue external layers (approx. 10% each) made of PE 100-RC raw material, black internal layer (approx. 80%) made of PE 100 raw material

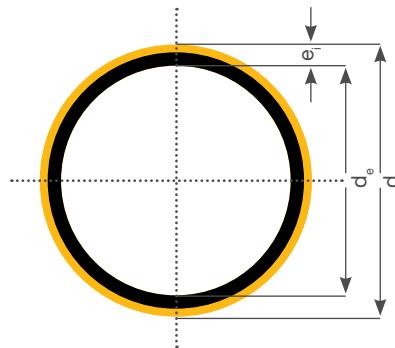

Pipes for gas supply systems

Made of raw material(s) PE 100

- a. single-layer pipes: yellow or orange

Made of raw material(s) PE 100-RC / PE 100-RC

- a. double-layer pipes: yellow or orange external layer (approx. 10%) made of PE 100-RC raw material, black internal layer (approx. 90%) made of PE 100 raw material

Joining methods

- compression fittings
- flange fittings
- butt fusion
- electrofusion welding

Basic colors, depending on application

- blue, navy blue, black with blue stripes - water pipes with a diameter of 20 to 630 mm for transporting drinking water, laid in the ground
- black, green, black with brown stripes - pipes for non-pressure sewage systems, pressure sewage systems, vacuum sewage systems in the ground and above the ground
- yellow, orange - pipes for gas systems

Pipes may be made in a different colour and/or with a different stripe colour.

Table 1**Plastics piping systems for water supply and for drainage and sewerage under pressure - Polyethylene (PE)****Nominal/mean external diameter; Maximum out-of-roundness (ovality) according to PN-EN 12201-2+A1:2013-1**

Table 4**Plastics piping systems for the supply of gaseous fuels - Polyethylene (PE)****Minimum pipe wall thickness with SDR 17,6, SDR 17, SDR 11 according to PN-EN 1555-2:2012**

Dimensions in millimetres

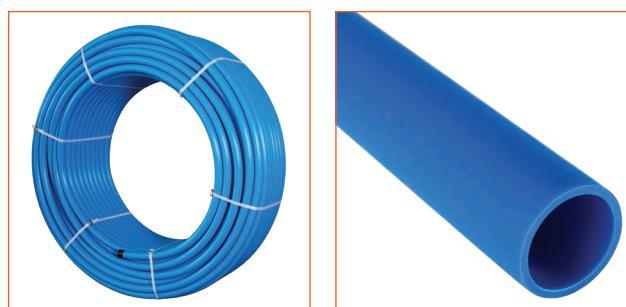

Nominal size DN/OD	Min. wall(s) thickness e_{min}^a		
	SDR 17,6 ^b	SDR 17	SDR 11
16	2,3 ^c	2,3 ^c	3,0 ^c
20	2,3 ^c	2,3 ^c	3,0 ^c
25	2,3 ^c	2,3 ^c	3,0 ^c
32	2,3 ^c	2,3 ^c	3,0
40	2,3	2,4	3,7
50	2,9	3,0	4,6
63	3,6	3,8	5,8
75	4,3	4,5	6,8
90	5,2	5,4	8,2
110	6,3	6,6	10,0
125	7,1	7,4	11,4
140	8,0	8,3	12,7
160	9,1	9,5	14,6
180	10,3	10,7	16,4
200	11,4	11,9	18,2
225	12,8	13,4	20,5
250	14,2	14,8	22,7
280	15,9	16,6	25,4
315	17,9	18,7	28,6
355	20,2	21,1	32,3
400	22,8	23,7	36,3
450	25,6	26,7	40,9
500	28,4	29,7	45,4
560	31,9	33,2	50,8
630	35,8	37,4	57,2

^a $e_{min} = e_n$ ^b EN 1555-2:2021-12 refers to SDR 11 and SDR 17 in Table No 2. In some countries, SDR 17,6 is defined.^c The calculated values of e_{min} have been rounded up to 2.3 mm for SDR 17,6 and 3.0 mm for SDR 11, respectively.

Pipes for water supply systems - PE 80

	Reference documents:	PN-EN 12201-2+A1:2013-12 HYGIENIC ATTESTATION
	PKWiU [Polish Classification of Products and Services]:	22.21.21.0
	Customs code:	3917 21 10
	Application:	- supply of pressurised water - supply of drinking water - supply of pre-treatment water - supply of water for other purposes - hydro-transport - other purposes
	Material:	PE 80
	Nominal pressure (PN):	PN 10 (SDR 13,6); PN 12,5 (SDR 11)
	SN:	SN 40 (SDR 13,6); SN 80 (SDR 11)
	Colour:	blue
	Q ext. [mm] - coils:	20, 25, 32, 40, 50, 63, 75
	Coil length [m]:	100, 150, 200
	Notes:	* Possibility of producing pipe in a different colour and/or with a different stripe colour * Possibility of producing pipe with a different coil length

INSTALLATION GUIDELINES FOR PE PIPES

The PE 80, PE 100, PE 100-RC single-layer polyethylene pipes and PE 100, PE 100-RC, PE 100-RC / PE 100, PE 100-RC / PE 100 / PE 100-RC multilayer co-extruded pipes intended for the supply of gaseous fuels, water and sewer under pressure.

1. Installation Guidelines

These instruction guidelines refer to the installation of soil pipes and PE line pipes used for pressure and gravity pipelines, in particular water, gas and sewer pipelines.

The maximum operating pressure of water and sewer pipelines corresponds to the nominal pressure (PN) of the pipe and depends on the material class, the pipe size series (SDR) and the construction safety factor (C) according to table A1 of EN 12201-2.

Pipes intended for the gas supply systems including PE100-RC/ PE100-RC multi-layer pipes with MOP 1.0 MPa within the range between 0°C and 20°C. For temperatures higher than 20°C, the maximum operating pressure (MOP) should be calculated taking into consideration the factors (DF) according to Table A.1 of EN 1555-5. For temperatures lower than 0°C, the critical pressure for rapid crack propagation determined for the expected operating temperature should be used to calculate the maximum operating pressure (MOP).

1.1. Terminology

Figure No 1 shows a trench cross-section and provides terms and definitions used herein.

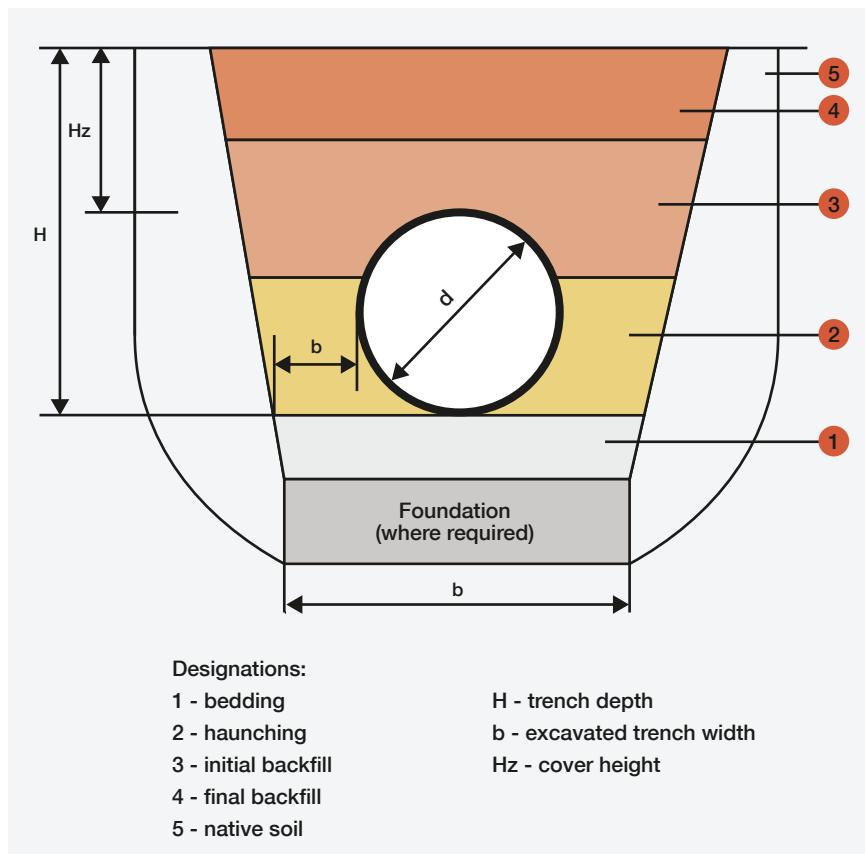

Figure No 1. Cross-section - terminology

1.1.1. Physical properties of PE pipes under load

PE pipelines, when exposed to certain loads, adapt to the surrounding substrate. This means that the final deflection value depends on the bedding and backfill of the pipeline.

Initial deflection occurs when the bedding and backfill is completed. This phenomenon builds up over time and takes the value of a long-term deflection. The observance of the installation guidelines set forth below will minimise this process.

1.1.2. Allowable deflections

The strength calculation methods contained in the EN 1295-1:2019-05 standard can be used to calculate the deformation of a pipe and to determine the allowable deflection. A pipe laid in a trench is subject to forces which cause deflection. This is called an initial deflection. This value, as a result of creeping, increases until a certain time, when it takes a final deflection value. The values obtained will therefore be our minimum and maximum deflection values. These values allow us to calculate the average deflection value, which is needed to calculate the allowable deflection value. A basic prerequisite for adequate strength is the quality of the pipe material.

As a result of the method of packaging used, the pipe ovalisation may occur (in pipes packed in coils, for instance, 50 metres).

1.2. Design considerations

1.2.1. General considerations

Soil conditions have a considerable impact on the trench construction and pipe installation. These conditions need to be determined before the commencement of design works and selection of the backfill designed for the specific type of soil.

Type of soil	Group of soils	To be used as initial backfills or final backfills
Loose	coarse-grained, gravel, sand and gravel mixes;	YES
	medium- and fine-grained gravel; sand and gravel mixes;	YES
	coarse-grained, gravel, sand and gravel mixes;	YES
Cohesive	medium- and fine-grained gravel; sand and gravel mixes;	YES
Organic	coarse-grained, gravel, sand and gravel mixes	NO
	medium- and fine-grained gravel; sand and gravel mixes;	NO

Table No 1. Types of soil and its use in construction works

Description	Soil compaction ratio			
	≤80	81-90	91-94	95-100
Standard Proctor compaction test	≤80	81-90	91-94	95-100
Blow test	0-10	43833	31-50	>50
Expected soil compaction achieved in the compaction classes are defined in this standard.		Low (N)	Medium (M)	High (W)
Loose soil	loose	moderately compacted	concentrated	highly concentrated
Cohesive and organic soil	soft	compacted	stiff	hard

Table No 2. Types of soil density

If no information is available regarding the subsoil, a compaction rate of 91-97% of the Standard Proctor compaction test (SPD) is assumed.

1.2.2. Types of pipe-laying methods in a trench

One of the most common ways of laying down pipes in a trench consists in preparing the ground by using a bedding material and backfill of the same material. The use of pipes with a nominal diameter less than or equal to DN 250 does not require applying a secondary backfill, i.e., a two-layer backfill.

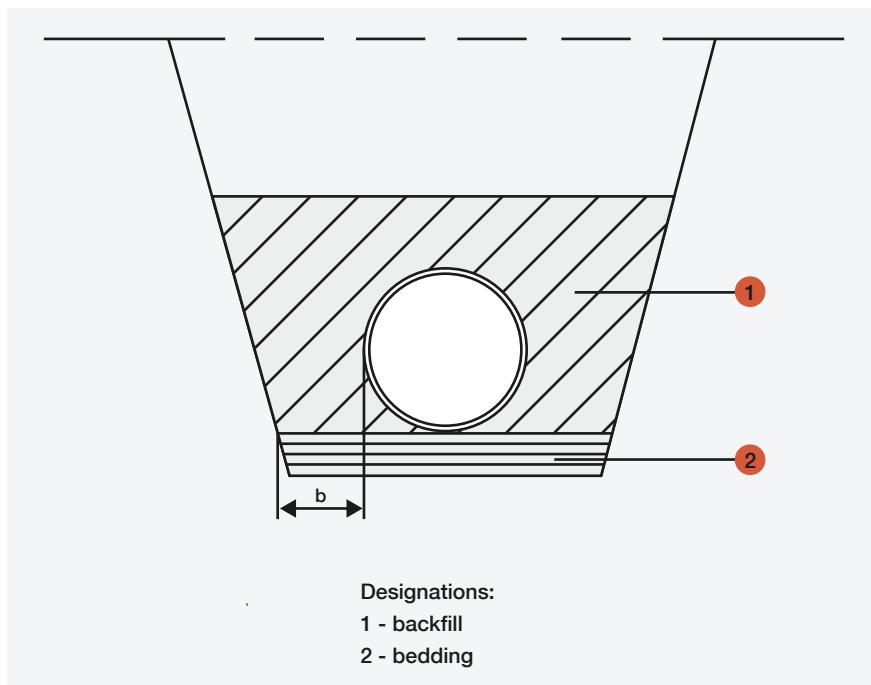

Figure No 2. Trench with uniform backfill layer

1.2.3. Laying multiple pipelines in a trench

Pipelines laid in parallel in one trench should have appropriate spaces to allow the backfill to be compacted using professional equipment. The minimum spacing between the pipelines should be 150 mm. The backfill between the pipes should be compacted to the same density as the backfill between the trench wall and the pipe. The only exception to the above is the laying of the pipeline in a stepped manner, in which the backfill should consist of loose material and be well-compacted.

1.3. Trench construction

1.3.1. Safety

Trench-related works should be performed in a non-life or health threatening conditions to the employees. The edges of the trench should be protected, if there is a risk of collapse or landslide. Foreign material must not get into the bedding and backfill, as this may reduce the quality of performance. The excavated material should be placed at a distance of not less than 0.5 m from the edge of the trench. Occupational health and safety rules and regulations must be observed during the excavation works.

1.3.2. Trench specifications

The width of the trench when laying down the pipeline depends on the ability to properly join the pipes in the trench and the compaction of the bedding and the backfill. For pipes below DN 300, typical values for the horizontal spacing between the pipe and the trench wall or adjacent pipe (see Figure No 2) are 200 mm. This is a theoretical value, due to the installation of the pipeline. When the pipeline is installed at great depths and in unstable soil, a wider trench may be required. In turn, in the case of a laying technology that eliminates or impedes human access (narrow-trench method), there is no need for excavating such a wide trench.

The depth of the trench must be determined in accordance with the design specifications. The key conditions are:

- purpose of the pipeline
- type and method of supply of the medium
- characteristics and size of pipes
- local conditions
- soil properties
- static and dynamic loads

In addition, the depth of the trench depends on the thickness of the bedding and the conditions within the working area, as well as the groundwater. It is not recommended that the excavation takes place before the installation of the pipes. The subsequent factor is low temperature. In such a case, the trench must be protected against freezing so that the laid pipe does not lie on a frozen layer of soil.

1.3.3. Trench bottom preparation and special conditions

The trench bottom should be properly prepared before the pipeline is laid. Bedding is of key importance as it protects the pipeline from excessive stresses, enabling it to minimise the risk of damage to the pipe. The thickness of the bedding may vary between 100[mm] and 150[mm], but should not be less than 50[mm]. The bedding must not be compacted and must be evenly distributed along the entire length of the trench. For this purpose, crushed rock gravel, gravel or sand may be used. If the substrate is made of soft material that can be formed freely and safely to ensure that the pipeline is properly aligned and is free of large rock objects, for instance, sharp stones or objects that could slipped, then bedding is not required.

In the case of special conditions such as:

- soil settlement
- risk of pipe flotation
- low temperatures
- other types of soil than non-cohesive soil
- soil loosening
- groundwater and flowing water

In situations referred to above, special design solutions are recommended, such as:

- application of reinforcement mats
- pipe insulation against low temperatures
- use of drains or other ways of draining water
- use of trench bottom reinforcement structures

1.4. Installation of the pipeline

1.4.1. Pipe storage

Pipes should be stored in a manner that is safe for the environment and the people staying in their vicinity. Pipes must be checked for damage and cleanliness before installation.

1.4.2. Laying down of pipes in the trench and changes in direction

The pipes should be laid down in the trench so that they lie loosely in the bedding over their entire length, which allows for their contraction or expansion. This is particularly important when weather conditions are unsuitable. Pipes must be installed in accordance with the instruction manual.

The direction of the pipeline may be changed using appropriate fittings.

1.5. Initial backfill and final backfill

1.5.1. Main method

When laying down pipes below DN 300, a uniform backfill layer is sufficient. The initial backfill should be brought up evenly on both sides of the pipe so that the additional stress is avoided. The initial backfill should be compacted using professional equipment. The final backfill may be made of native soil, if it meets the relevant requirements. The final backfill should be placed in even layers and compacted.

1.5.2. Laying area of the pipeline

The type and quality of the initial backfill is mainly affected by the depth on which the pipes are to be laid, the properties of the native soil and the stiffness of the pipe. A uniformly graded material should be used, however, if the initial backfill material has a predominance of one material fraction, then a particle size as indicated in Table No 3 is recommended.

Nominal Diameter DN	Maximum particle size
DN < 100	15
100 ≤ DN < 300	20
300 ≤ DN < 600	30
600 ≤ DN	40

Table No 3. Maximum particle sizes

Native soil may be used as initial backfill, if it meets the appropriate requirements, i.e.:

- is free from contaminants such as waste, wood, asphalt
- if compaction is required, then the material is subject to compaction
- is not a frozen material
- does not contain particles larger than those contained in Table No 3 and does not contain lumps of soil larger than double the size for the pipe application in question

Soils characterised by high plasticity index, as well as fine-grained soils are not considered good initial backfill material, unless this has been taken into consideration during the pipeline design. The strength of the initial backfill depends mainly on the degree of compaction and the type of raw material used.

The strength conditions of the pipes within the initial backfill zone depend on the material used for this purpose and the degree of compaction. Degrees of soil compaction are determined according to the standard Proctor compaction test, obtained in three compaction classes, appropriate to the soil used.

Compacted class	Description	Soil group used for initial backfill				
		English	4 SPD [%]	3 SPD [%]	2 SPD [%]	1 SPD [%]
N	Not	Not	75-80	79-85	84-89	90-94
M	Moderate	Moderate	81-89	86-92	90-95	95-97
W	Well	Well	90-95	93-96	95-100	98-100

Table No 4. Soil compaction according to the Standard Proctor compaction test

1.5.3. Final backfill

If the depth of the trench above the pipe is more than 30 cm, this trench can be backfilled with native soil. It is also important that the final backfill material is susceptible to compaction, if required, with a maximum particle size of no more than 2/3 of the compacted layer.

In the case of high-traffic areas, it is required that the final backfill is well-compacted. In the case of low-traffic areas, the final backfill may be low-compacted.

1.6. Quality control

The soil compaction should be controlled by at least one of the following methods:

- supervision over compaction procedures
- initial pipe deflection test
- soil compaction test

The initial backfill and final backfill material must be compacted to the same degree as the soil immediately adjacent to the trench.

1.7. Safety precautions

When laying down the pipeline, the bedding must not be disturbed. In addition, measures must be taken to prevent the pipe flotation. Special attention must be paid when removing the formwork or other trench protection systems. These operations should be carried out together with the excavation of the trench and the compaction of the individual layers. If this is not possible, it is recommended to use pipes prepared for this purpose.

When making the initial backfill, the pipe must be protected from falling objects or unwanted native soil. The initial backfill and final backfill should be compacted to ground level. It is not advisable to compact the initial backfill directly above the pipe, if it has insufficient thickness.

1.8. Laying down pipes in the trench

One of the two methods of storing PE pipes is to coil them. In this way, a greater length of pipe is joint-free. When pipes in coils are stored, the pipe ovalisation occurs. In order to restore the pipes to their previous shape, pipe straighteners are used. If the ends of the pipe have an oval shape, calibrators are used to restore them to their original shape. The use of electrofusion fittings is recommended when joining pipes in coils. During electrofusion, coupler fittings must be used. Thanks to the properties of PE100-RC pipes, they can be used for various types of installation, such as drilling and jacking.

2. Control and test

2.1. Control

During acceptance, the pipes should be checked by the purchaser or the purchaser's representative. The markings and condition of pipes must be checked. In addition, it is important to verify whether the pipes are damaged. Any damaged pipes should be put aside and the damaged section of pipe cut off or returned to the manufacturer.

2.2. Test

Before pressure testing begins, it is important to ensure whether the pipeline is properly laid down in the trench and whether the fittings and bends are able to withstand rated pressure by the proof test. The proof test should be carried out in accordance with the relevant standard. Any possible exceptions are included in the system standard.

Pipeline requirements and tests included in the standard: EN 805 introduces methods for the leakage test of PE pipelines to be carried out in accordance with the procedure contained in Annex A.27 of PE-EN 805.

The contents of this Annex are set out below.

A.27 Main pressure test

A.27.1 General provisions

This alternative method for viscoelastic pipes (such as polyethylene and polypropylene pipes) is based on the fact that the characteristic creep of the material is not sufficiently taken into consideration in the main pressure test. Therefore, a specific procedure is set out below.

A.27.2 Test procedure

The entire test procedure consists of the necessary initial phase, which includes a relaxation period, an integrated pressure drop test and a main test phase.

A.27.3 Preliminary phase

The completion of the preliminary phase is a prerequisite for the main test phase.

The aim of the preliminary phase is to specify the initial conditions for the volume variation as a function of pressure, time and temperature.

In order to avoid erroneous test results at the main test phase, the following rules should be applied for the implementation of the preliminary phase::

- after flushing and venting, reduce pressure in the pipeline to atmospheric pressure; such condition is to be held for 60 minutes in order to release any pressure-related stress; do not allow air to enter the test section;
- after this relaxation period, raise the pressure continuously and quickly (not less than 10 minutes) to the System Test Pressure (STP). Maintain STP for a period of 30 minutes by pumping continuously or at short intervals. During this time, carry out an inspection in order to identify any obvious leaks;
- after 30 minutes, one-hour relaxation period is required (without pumping) during which the pipeline may expand due to visco-elastic creep;

- reduce the pressure at the end of this period.

If the preliminary test is completed successfully, control the test procedure. If the pressure has decreased by more than 30% of STP interrupt the preliminary test and de-pressure the test section. Check the test conditions (for instance, influence of temperature, indication of leakage) and only restart the test procedure after a relaxation period of at least 60 min.

A.27.4 Integrated pressure drop test

The results of the main test phase can only be assessed, if the remaining volume of air in the test section is adequately low. The following steps should be taken:

- reduce rapidly the remaining actual pressure measured at the end of the preliminary phase by discharging water from the system to produce Δp of 10 % to 15 % of STP
- measure precisely the removed volume ΔV ;
- calculate the allowable water loss ΔV_{\max} using the following formula and check that the removed volume ΔV does not exceed ΔV_{\max}

$$\Delta V_{\max} = 1,2 \cdot V \cdot \Delta p \left(\frac{1}{E_w} + \frac{D}{e \cdot E_R} \right)$$

ΔV_{\max} is the allowable water loss in litres;

V is the volume of the tested pipeline section in litres;

Δp is the measured pressure loss in kilopascals;

E_w is the bulk modulus of water in kilopascals;

D is the internal pipe diameter in meters;

e is the wall thickness of the pipe in meters;

E_R is the modulus of elasticity of the pipe wall in the circumferential direction in kilopascals;

1,2 is an allowance factor (e.g., for air content) during the main test phase.

For the interpretation of the result, it is important to use the exact value of ER considering the temperature and the duration of the test. Especially for smaller diameters and shorter test sections Δp and ΔV should be measured as accurately as possible.

If ΔV is more than ΔV_{\max} , interrupt the test procedure and vent again after the pipeline has been depressurized.

A.27.5 Main test phase

The visco-elastic creep due to the stress caused by STP is interrupted by the integrated pressure drop test. The rapid decrease of the pressure leads to a contraction of the pipeline. Observe and record for a period of 30 minutes (main test phase) the increase of pressure resulting from the contraction. The main test phase is considered to be successful, if the pressure curve shows an increasing tendency and does not decrease at any time of this 30-minute period, which is normally long enough to get a good indication (fig. no 3). If during that period the pressure curve shows a falling tendency, it indicates a leak within the system.

In case of doubt, extend the main test phase to 90 minutes. In that case the pressure loss is limited to 25 kPa from the maximum value occurring within the contraction phase.

If the pressure drops by more than 25 kPa, the test fails.

Rectify any defect in the installation revealed by the test and repeat the test.

The repetition of the main test phase may only be done upon carrying out the whole test procedure including the relaxation period of 60 minutes in the preliminary phase.

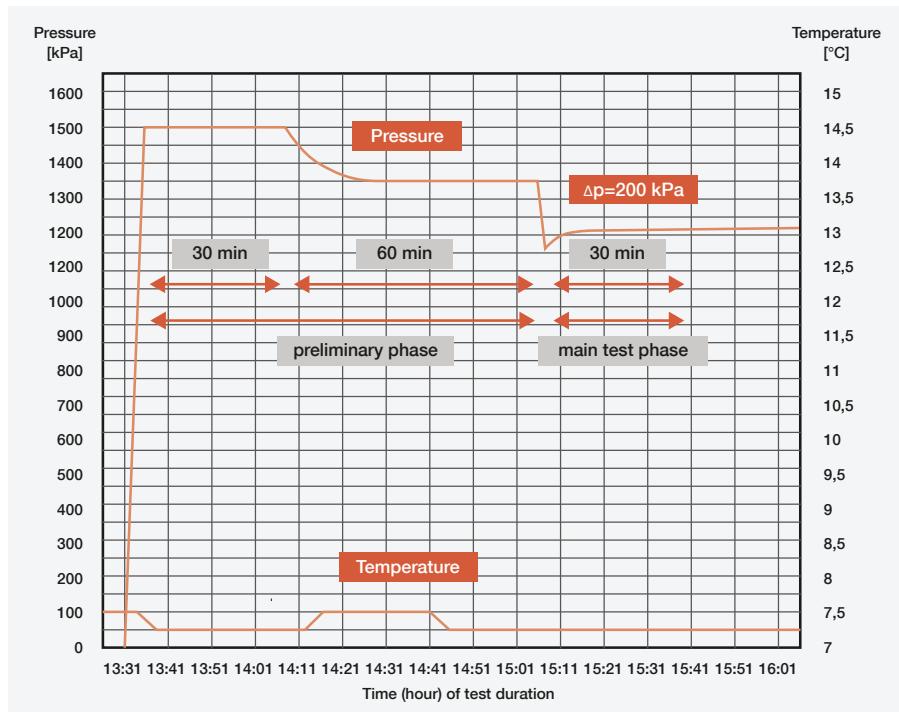

Figure No 3. Example of pressure test scheme (time/hour of test)

2.3. Leakage test of the gas pipeline

The leakage test of polyethylene gas pipelines should be carried out in accordance with PN-92-M-34503 "Gas pipelines and gas installations. Testing of pipelines".

The test pressure level used does not induce as much PE creep (as in the case of water pipelines). The compressibility of the gas used in the sample means that changes in piping volume have no noticeable effect on changes in internal pressure.

Due to the fact that polyethylene is a good insulator, once the pipeline has been filled with compressed air using a compressor, the actual leakage test may start once the temperature of the pipe and the air in it has dropped to ambient temperature. This may take several hours. Failure to meet this condition may result in a drop in internal pressure, not only as a result of the leak, but as a result of the gas transformation effect, in which, at a constant volume of the section of pipeline under test, a drop in gas (air) temperature is accompanied by a drop in pressure.

3. Pipe joining methods

Various methods of joining the pipeline are used during installation, ranging from mechanical joining such as compression fittings or butt fusion to electrofusion welding. The use of methods of the pipe joining depends on the conditions in which it is to be made and the purpose of such a joint. Such joints should be made in accordance with the procedures recommended by the manufacturers of these fittings.

3.1. Compression fittings

Compression fittings are recommended when joining PE pipes in sizes Ø25 to Ø63. Compression fittings are also used when joining pipes to steel components and fittings. This also depends on the dimension of the fitting and its type. Both the possibility of making multiple joints and the simplicity of its manufacture are in favour of compression fittings.

3.2. Butt fusion

Before proceeding with the butt fusion, it is recommended to:

- prepare the welding area by setting up the butt fusion machine, the generator unit, or by setting up a tent on a dry site; if the area requires it, place a film or board under the butt fusion machine;
- place the welded pipe sections on rollers (this reduces the forces acting on the pipe);
- secure the opposite ends of the pipe sections to be joined with plugs to prevent any possible air flow through the pipes during butt fusion;

- clean the pipe ends (or fittings) over a length of approx. 0.1[m], as well as the heating plate and the shaping machine from dirt;
- fix the pipes or fittings in the butt fusion machine clamps in such a way that a misalignment of no more than 10% of the wall thickness is obtained;
- prepare and align the weld faces with a shaping machine to remove the oxidised layer and to make the faces of the two pipe sections adjoin with each other;
- make the weld and make an assessment on the basis of the following formula.

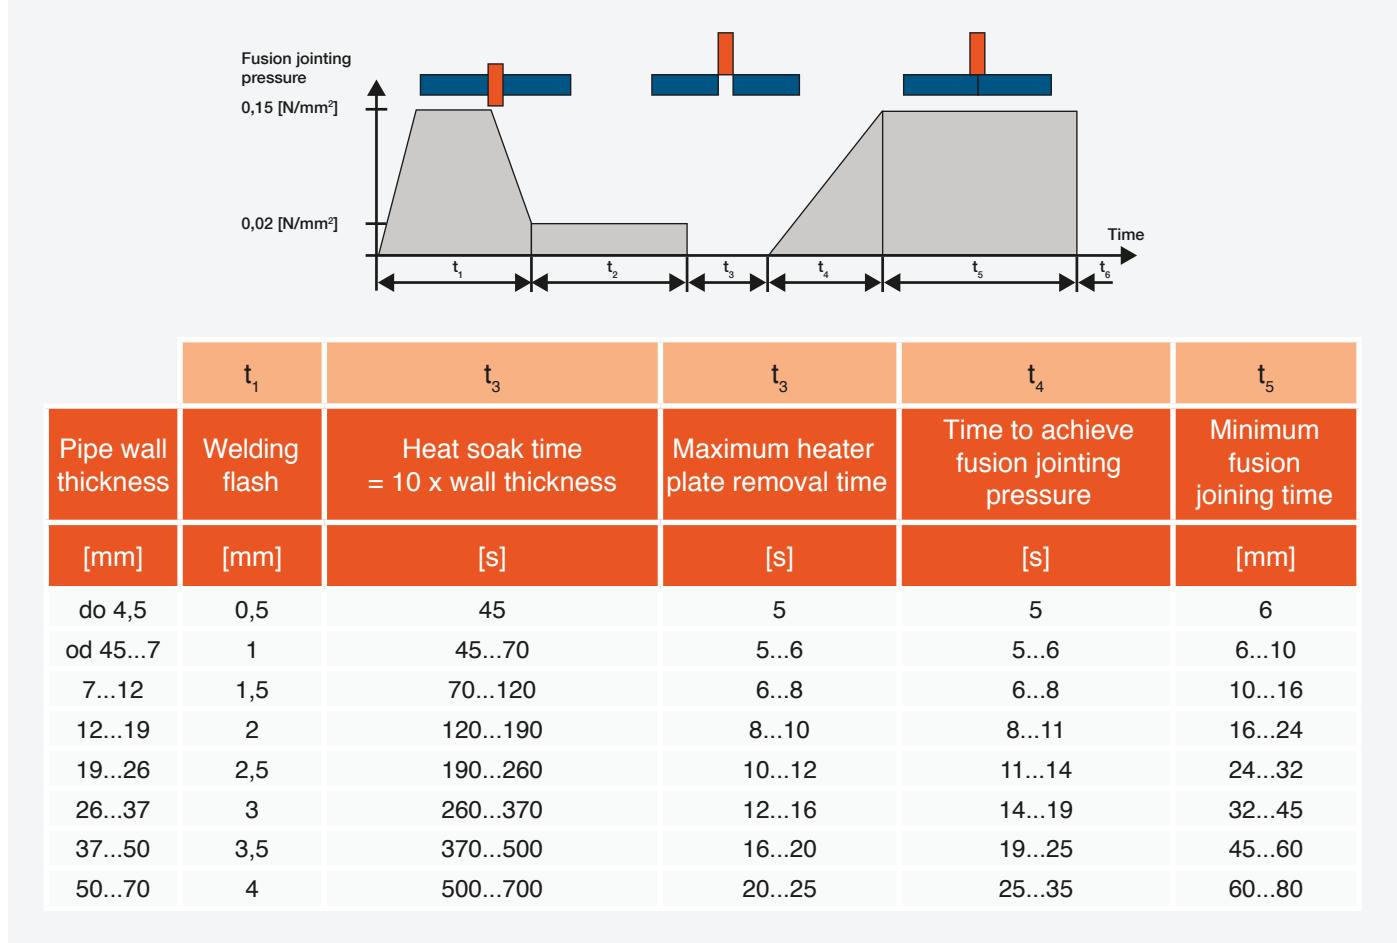

Figure No 4. Butt weld diagram

Assessment criteria for the butt weld quality:

- the width of the "B" welding flash should have the following value:

$$B = (0,68 \div 1,0) * e \quad *e \text{ where: } e - \text{wall thickness [mm]}$$

- the difference in width of the welding flash rolls should not exceed 20% of the width of the "B" welding flash, i.e.,

$$S_{\max} - S_{\min} < 0,2B$$

- the groove between the rollers, the "k" value must not be less than zero, i.e.,

$$k \geq 0$$

- the wall offset of the pipes to be joined, the "v" value should not exceed 10% of the wall thickness;
- the shape of the welding flash, the minimum and maximum width of the welding flash must comply with the following values:

$$B_{\min} \geq 0,9 * B_{sr} \quad B_{\max} \leq 1,1 * B_{sr} \quad B_{sr} = 0,5 * (B_{\min} + B_{\max})$$

- alignment of welded pipes - $\Delta m \leq 1$ [mm] over a length of 300 [mm].

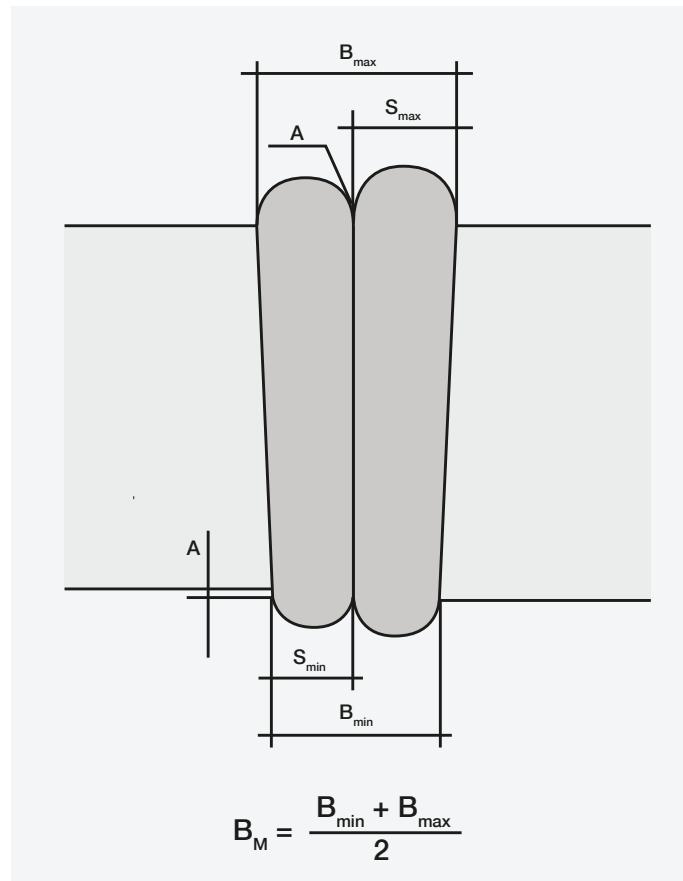

Figure No 5. Test scheme for correct joining

The quality of the weld is also affected by:

- keeping the cleanliness of the surfaces to be joined
- proper preparation of the joining procedure
- compliance with welding parameters
- proper relaxation of pipes

3.3. Electrofusion welding

The electrofusion welding procedure is as follows:

1. clean the pipe, cut the pipe at right angles, remove any burrs and shavings
2. remove the oxidised surface layer of the pipe using a suitable scraping tool to the length that is inside the fitting (it is important not to take off too much material)
3. clean the welding surface with a welding wipe containing degreasing fluid (ethanol)
4. mark the insertion depth of the fitting
5. remove the fitting from the packaging; take care not to touch the inside of the fitting
6. insert the end of the first pipe and assess position, insert the end of the second pipe
7. carry out welding procedures according to welding machine instructions and the instructions placed on the packaging of the fitting
8. assess the weld after the welding process, remove the welding machine from the fitting and leave the pipe to cool down
9. perform a pressure test

TRANSPORT, MOVEMENT AND STORAGE OF POLYETHYLENE PIPES PRODUCED BY TT PLAST S.A. - INSTRUCTIONS

When transporting and storing the pipes, be careful not to damage them. Polyethylene is a material with relatively low mechanical resistance to scratches.

PIPE TRANSPORTATION:

1. Vehicles with a level and flat floor, nail-free and other irregularities in the load compartment or specialised vehicles should be used to transport the pipes.
2. The side supports should be flat, without sharp edges.
3. The largest diameter pipes should be laid at the bottom of the load compartment.
4. Pipes should not be transported outside the load compartment of a vehicle in a section greater than five times their nominal diameter DN expressed in metres, or a length of 2 m, whichever value is less.
5. Special care should be taken during loading and unloading at low ambient temperatures, as the impact resistance of plastic products decreases at low temperatures.
6. The loading height during transport should be such as it does not damage the pipes and ensures their stability.
7. Pipes should be secured against movement during transport.
8. Products should be transported in accordance with current transport regulations.

PIPE MOVEMENT:

1. Special protective measures must be taken to prevent damage to the pipes when they are moved.
2. As a result of contact with sharp-edged objects, dropping, falling, dragging along the ground, plastic pipes can be damaged.
3. When loading or unloading pipes using a crane, slings made of soft ropes (nylon, cotton and hemp ropes, etc.) must be used.
4. Steel ropes or chains must not be used. Improperly used metal beams, slings, hooks or chains may damage the pipe.
5. When loading or unloading pipes using a forklift, it is important to ensure that this industrial truck has smooth forks. Special care must be taken when lifting (lowering) pipes in order to avoid damage.
6. Smaller diameter pipes (for instance, up to 160 mm) may be handled manually on site. It is not allowed to drag the pipes along the ground or to drop or roll them.
7. At low temperatures, the impact resistance of plastic pipes decreases. Special care should be taken when moving the pipes.
8. The utmost care must be observed when unwinding pipes in coils, as the released end of the pipe unwinds with considerable force.

STORAGE OF PIPES:

1. Pipes must be stored on a level, smooth surface, preferably wooden, or a surface free of sharp objects, stones or protrusions that could damage the pipes.
2. Straight pipes, pre-packed in bundles using wooden frames, can be stored in layers up to a height of 3 m, with the frame of the higher bundle resting on the frame of the lower bundle.
3. Pipes in coils may be stored horizontally with a storage height of up to 1.5 m (requirement for gas pipes) or vertically in a single layer - a vertically standing coil, which may not be additionally loaded.
4. Unpacked pipes may be stored in a pile with a maximum of 7 layers and a height of no more than 1 m, with the bottom layer resting on wooden sleepers and secured on the sides with wooden supports to prevent displacement. In the case of storing pipes of different stiffness, the pipes with the higher stiffness should lie at the bottom. Spacing between sleepers and supports should be 1÷2m.
5. Pipes in coils with nominal diameters equal to and greater than DN 90 should be stored vertically in purpose-built racks.
6. When pipes are stored in racks, their design should provide adequate support to prevent permanent deformation of the pipes.
7. Pipes should not be stored in the immediate vicinity of fuels, solvents, oils, greases, paints or heat sources.
8. Pipes should be stored in a closed and covered premises in order to protect them against direct weather conditions. The free flow of air must be ensured. It is not allowed to store pipes in areas directly exposed to sunlight (UV radiation), leading to degradation of the plastic and loss of mechanical properties.
9. The maximum storage time for pipes not protected against sunlight is 3 months. The use of pipes after the aforementioned period is only possible under the full responsibility of the customer. The storage temperature should not exceed 45 °C.
10. In the case of extreme storage conditions, it is required to meet special requirements related to the storage of pipes.
